STEM and the Local Economy: Do Regions Reap the Benefits of a STEM-Educated Workforce?

The pursuit of science, technology, engineering, and math (STEM) degrees has moved from one of personal interest or professional ambition to a matter of economic imperative and public priority. The policy assumption is clear: Economies benefit when scientists make discoveries, engineers solve problems, and computer experts program solutions. The places that can attract or develop these professionals are deemed the winners in today’s technology-driven economy. The certainty of this conventional wisdom has driven countless interventions targeted at growing the local STEM “pipeline.” Yet, an important question remains: Does a greater supply of STEM-degreed workers bring about the expected economic gains for regional economies? Largely imitative efforts to expand the ranks of highly educated STEM workers neglect important differences in regional demand for such skills. This approach also neglects the importance of other skill sets to regional competitive advantage. Understanding the best way to invest in regional human capital requires a broader understanding of regional human capital differences.

Shifting the Focus to Occupational Competencies

This article highlights research in The STEM Dilemma: Skills That Matter to Regions, which was recently published by the Upjohn Institute (see p. 7). The book looks at the regional workforce through the lens of the knowledge, skills, and abilities (KSAs) associated with regional occupations. This fine-grained approach uses data in the Occupational Information Network (O*NET) database to identify differences in regional human capital concentrations. The O*NET database scores the importance and the required level of 120 individual KSA attributes for each occupation. Matching the occupational KSA attributes to wage and employment data available from the Occupational Employment Statistics (OES) enables examination of the actual human capital differences present in regional economies and answers some important questions:

1. To what extent do STEM occupations drive modern regional economies?
2. Do STEM occupations provide better wages for regional employees?
3. What other KSAs represent valuable regional human capital?
4. Is there a relationship between the KSAs in demand by regional occupations and the welfare of the region itself?

Guided by the sharp policy focus on STEM study, this research set out to explore the effect of STEM skill concentrations on regional well-being.

Educational attainment is associated with higher wages but does not necessarily have significant effects on other measures of regional well-being.

However, because employers often say they want workers who can communicate effectively, solve problems, think critically, and motivate others, the research also examined the contribution of “soft” skills to the regional economy. Of the 120 KSAs included in the O*NET database, this study sorted 35 into a bundle representing STEM competencies and 50 into a bundle representing soft skills. What is clear among the bundle of STEM KSAs is the importance of math and computer knowledge, as well as more “hidden” STEM competencies (Rothwell 2013), such as mechanical skills and operations monitoring. Within the bundle of soft KSAs, communication skills, specifically oral expression and comprehension, are important, as well as skills associated with listening and understanding.
Table 1 calls into question the wisdom of largely imitative policies aimed at growing the STEM pipeline. Not all places have the same STEM demand or capacity to absorb STEM supply. This difference also raises doubt as to whether the individual benefits from human capital development (higher wages) “roll up” to improve regional economic well-being overall, as so many policies that promote college-going and STEM study assume.

A Complex Relationship: Human Capital and Regional Economic Well-Being

To examine the relationship between regional human capital concentrations and regional economic well-being, a region’s distribution of employment across the four categories was regressed against data from the American Community Survey and Moody’s Analytics. Guided by Andreason (2015), this study adopts a broader view of regional economic well-being beyond the common focus on wages. In addition to wages, gross regional product (GRP), GRP per capita, per capita income, and poverty
rate were used as dependent variables in the study. Each MSA’s labor force participation rate, share of employment in manufacturing, population change from 2010–2013, and ratio of median house value relative to the U.S. median house value were entered as control variables. A common measure of human capital—the share of the adult population with a bachelor’s degree or higher—was also regressed on the data for comparison, revealing that the models with the occupational competency measures had greater explanatory power. Moreover, the education variable was only positively associated with two well-being indicators: median wage and per capita income.

All the occupational human capital categories affected regional median wage in the way human capital theory suggests. A higher concentration of employment in occupations requiring any kind of above-average KSAs was associated with higher regional wages. The practical implication of this finding is that a region may see improved economic well-being from promoting STEM skill development, but the region may also benefit from focusing on soft skill development. Another important finding is that having a high proportion of Low STEM/Low Soft employment was a substantial drag on the regional economy. Such regions tend to have lower (or negative) growth in GRP, lower productivity, and lower per capita incomes. This indicates a need for greater policy focus on addressing issues surrounding jobs that are important to the economy but that come with low pay and limited benefits for workers and present significant challenges to regional well-being.

Only one skill category—High STEM/Low Soft—was shown to have a statistically significant impact on all five indicators of regional economic well-being. These insights should help policymakers shape more targeted and effective place-based policies. Regional human capital development should increase the supply of valuable talent, provide employers with access to appropriately skilled workers, and connect workers to opportunities that best align with their talents. Key insights from the research include the following:

- Educational attainment is associated with higher wages but does not necessarily have regional well-being. These insights should help policymakers shape more targeted and effective place-based policies. Regional human capital development should increase the supply of valuable talent, provide employers with access to appropriately skilled workers, and connect workers to opportunities that best align with their talents. Key insights from the research include the following:

**Conclusion**

This research clarifies how human capital development functions in the larger economy and how differences in human capital deployment impact economic well-being. In broad terms, human capital development accrues benefit to regions, but the effect is not as straightforward or as broad-based as typically assumed. Some human capital categories are statistically associated with some aspects of regional well-being while others are not.

**Note:** A blank cell indicates that the impact was not statistically significant from having no impact.

* The percentages do not add up to 100% because not all occupations have been mapped by O*NET; the OES survey does not include self-employed workers; certain government occupations are not included in this analysis; and the OES suppresses data at the detailed occupational level if inclusion of the data may reveal specific establishments in an MSA.

Race to the Bottom?
Local Tax Break Competition and Business Location

Evan Mast

State and local governments in the United States spend $45–$80 billion each year on programs that encourage economic development in a particular geographic area (Bartik 2017; Kline and Moretti 2014). These programs, often called place-based policies, typically offer tax breaks in an effort to attract businesses or encourage the growth of existing businesses. These range from huge subsidies like the $3 billion that Foxconn recently received from the state of Wisconsin to small programs that target local small businesses. A crucial feature of place-based policies is that they are very decentralized—state and local governments account for 80 percent of total spending.

This article highlights findings from a recent paper that focuses on two potential effects of decentralization in business tax breaks (Mast 2017). First, competition between subnational governments could increase total tax exemptions. Second, local control of tax breaks could cause firms to choose locations where they produce more value for the community. The latter may occur because jurisdictions with more to gain from landing a firm offer larger exemptions, sending a signal that could improve the match quality between towns and firms.

These two effects are important for evaluating policies that restrict which governments can offer tax breaks, such as proposals to ban state exemptions or the recent moratorium on some local exemptions in the Phoenix area. Such proposals have attracted attention recently, as Amazon and Foxconn have conducted well-publicized searches for locations for new expansions.

The Importance of Local Taxes For Businesses

This article focuses on local, rather than state, government tax breaks. State and local taxes are a large component of the total business tax burden—a 2014 estimate pegged total state and local businesses taxes at $688 billion versus total federal corporate income tax revenues of $320 billion (Phillips et al. 2015).

While state incentive packages for national searches are more heavily publicized, local tax breaks are important in many cases. First, most firms do not search nationally when considering an expansion or relocation. Second, even for firms conducting national searches, there is often a second, local stage to their search. For example, Foxconn considered several sites in Racine and Kenosha Counties after announcing their intention to build in Wisconsin. Local tax breaks also amount to large sums—approximately $700 million in New York State in 2013.

The Effect of Competition on Local Tax Breaks

To begin, I study spatial competition between local governments in New York State. Do governments offer

ARTICLE HIGHLIGHTS

- Competition from nearby local governments increases business tax breaks.
- Simulations suggest that businesses typically locate in the same towns that they would have chosen if local tax breaks were not allowed.

significant or desirable effects on other measures of regional well-being.
- Above-average STEM KSAs are associated with increased regional well-being, but “high” may not be as high as is typically assumed. Not all value comes from college-degreed STEM occupations. These results show the importance of many technician and mechanical jobs that often are overlooked or ignored in articles, research, and policy on the economic importance of STEM jobs.
- Efforts to help displaced workers may be more effective if they explore the skills associated with previous occupations and try to match workers to occupations with similar skill needs. Helping workers make the case for cross-cutting skills to regional employers could be a more effective economic development strategy than investment in big leaps of unrelated retraining.
