## **A Frontline Decision Support System for One-Stop Centers**

Randall W. Eberts, Christopher J. O'Leary, and Kelly J. DeRango  
*W.E. Upjohn Institute for Employment Research*

The Workforce Investment Act (WIA) of 1998 emphasizes the integration and coordination of employment services. Central to achieving this aim is the federal requirement that local areas receiving WIA funding must establish one-stop centers, where providers of various employment services within a local labor market are assembled in one location. This arrangement is expected to coordinate and streamline the delivery of employment-related programs and to meet the needs of both job seekers and employers more effectively than did the previous arrangement.

Successful implementation of the one-stop system requires new management tools and techniques to help staff meet the challenges presented by the one-stop environment. A major challenge is the large volume of customers expected to use the system. Increased use of services is expected because of a reduced emphasis on program eligibility as a condition for participation in the workforce investment system. Nonetheless, resources for comprehensive assessment and counseling are limited, and frontline staff have few tools with which to help them make decisions.

A prime challenge for frontline staff is to determine which set of services best meets the needs of customers who enter a one-stop center, and to do this in a consistent, rational, and efficient manner. However, not all one-stop center staff may have sufficient experience to make informed decisions for clients participating in the wide variety of programs offered. The coordination of services under the new one-stop arrangement now requires staff to serve customers with various back-

grounds, whereas prior to the creation of one-stop centers, staff typically concentrated in a single program area and saw clients with similar barriers. An additional complication is the emphasis that WIA places on performance outcomes and accountability. WIA requires that program success be measured by employment, earnings, job retention, and knowledge or skill attainment.

The Frontline Decision Support System (FDSS) is a set of administrative tools that is being developed to help frontline staff successfully perform their duties within one-stop centers. The goal of these tools is to assist staff in quickly assessing the needs of customers and in referring customers to services that best meet their needs. FDSS includes new tools to help customers conduct a systematic search for jobs that offer the best match, to set a realistic wage goal, and to assist staff in determining which one-stop center services are likely to be effective in meeting the needs of specific customers in becoming employed.

The W.E. Upjohn Institute for Employment Research is working to design, develop, test, and implement an FDSS in pilot sites within the states of Georgia and Washington. These states were chosen because they offer an opportunity to demonstrate the adaptability and capability of the FDSS within different one-stop center operating environments. Recognizing that the computer operating systems for the one-stop centers vary among states, FDSS is being designed so that states can easily integrate the decision tools into their specific computer systems. The FDSS tools are designed to be used within the data-retrieval and display systems being implemented by states for their one-stop centers.

The design and implementation of FDSS is a cooperative effort of the U.S. Department of Labor (DOL), the state employment agencies of Georgia and Washington, and the W.E. Upjohn Institute. After testing the system at sites in these states, DOL intends to offer FDSS tools to other interested states. With research and operations carried out within the same organization, the Institute is uniquely positioned to coordinate the analytical and administrative tasks required to develop, test, and implement FDSS within the one-stop centers. The Institute not only conducts employment-related research but also administers the state and federal employment programs that are the responsibility of the local Workforce Investment Board. The Institute has served as the administrator of federal and state employment-related programs for the Kalamazoo, Michigan, area since the early 1970s. During that period,

the Institute has operated programs under the Comprehensive Employment and Training Act, the Job Training Partnership Act, and currently WIA.

The purpose of this chapter is to present an overview of FDSS and to give examples of the analysis underlying some of the decision algorithms that are the backbone of the FDSS tools. In the next section, we summarize the overall concept of FDSS and provide an outline of the typical client flow through the one-stop centers. We then proceed to describe examples of the statistical models that are used in the systematic job search module of FDSS. These models include estimates of the likelihood of finding a job in the industry in which the worker was employed prior to displacement and estimates of the earnings that a displaced worker might expect when looking for reemployment. We next outline the algorithm that identifies occupations that are related to a worker's occupation held prior to displacement. The purpose of this algorithm is to provide workers who have been frustrated by their initial job search efforts with a list of occupations that have skills and attributes similar to the ones embodied in jobs held prior to displacement. This list of related occupations allows a worker to conduct a more systematic job search effort. Finally, we describe the features of the second FDSS module, the service referral module, which is currently under development. This module assesses the most effective set of services based on the individual's characteristics and employment history.

## **FRONTLINE DECISION SUPPORT WITHIN ONE-STOP CENTERS**

FDSS provides one-stop center staff with client information and assessment tools that can be used in helping clients conduct a systemic job search and in determining the set of employment services that should work best for specific clients. To understand the role of FDSS, it is first necessary to provide a brief overview of one-stop centers, the services they provide, and the way in which staff interact with customers. The operation of one-stop centers varies among states, and even among local areas within states. Consequently, we can provide

only a stylized description of one-stop centers, which suffices for our purpose of describing how FDSS can be integrated into the general approach of these centers.

As mandated by WIA, one-stop centers provide a central physical location for the provision of services offered by federal and state employment programs. WIA requires that the following programs be included: unemployment insurance, employment service, dislocated worker and youth training, welfare-to-work, veterans' employment and training programs, adult education, postsecondary vocational education, vocational rehabilitation, Title V of the Older Americans Act, and trade adjustment assistance. Other programs may also be included under the one-stop center's umbrella of services. One-stop centers are designed to serve customers within local Workforce Investment Areas, which usually encompass the population of one or more counties within a state. Workforce Investment Areas with large populations or which span a large geographical area may choose to establish several one-stop centers. WIA required that each state develop a system of one-stop centers that would be fully operational by July 2000. Most states met this target date.

Services provided by the one-stop centers are divided into three levels: core, intensive, and training. Services within each level are characterized by the amount of staff involvement and the extent to which customers can access the service independently. Core services typically have the broadest access and the least staff involvement of the three categories. Many core services are accessible on a self-serve basis. All adults and dislocated workers can access core services, which include assessment interviews, resume workshops, labor market information, and interviews for referral to other services.

Intensive services, the next level of services within a one-stop center, require a greater level of staff involvement, and access is more restricted than for core services. Services within the intensive category include individual and group counseling, case management, aptitude and skill proficiency testing, job finding clubs, creation of a job search plan, and career planning. Training services, the third and final level of services offered by one-stop centers, use staff most intensively and are open to customers only through referrals. One-stop centers typically contract with organizations outside the centers to provide these services. Included in this set of services is adult basic skills education, on-the-job training, work experience, and occupational skills training.

Several challenges must be surmounted for successful implementation of one-stop centers. The first is the large volume of customers expected to use the centers. Nationally, nearly 50 million people are expected to use the one-stop centers each year. Center staff will be faced with serving more people than under previous organizational arrangements. The move toward integrating services raises another challenge: staff will be asked to serve clients who may have unfamiliar backgrounds and needs. For instance, a staff person who worked extensively with dislocated workers under JTPA may now be asked to work with welfare recipients as well. Job search techniques and services that are appropriate for dislocated workers may not be as effective for welfare recipients. The lack of prior experience counseling welfare recipients may hinder staff effectiveness. WIA does not provide additional resources for staffing or significant cross training.

Another challenge for operators of one-stop centers is to refer customers to services in the most effective manner. The efficiency and effectiveness of a center's operations are driven by the difference in cost of providing the three levels of services. As shown in Figure 12.1, the cost of services increases dramatically and the anticipated number of participants falls as one moves from core services to training services. Therefore, the ability to identify the needs of individuals and to refer them to the appropriate service as early as possible in the process will determine the cost-effectiveness of the one-stop centers. FDSS is designed to address the need for more informed decision-making and the strategic referral of services.

FDSS includes two basic modules or sets of tools. Figure 12.2 shows how the two modules fit into the operation of the one-stop center. The first is the systematic job search module. This set of tools provides clients with customized information about several aspects of the job search process, with the purpose of assisting them in conducting a more systematic search. Initial job search activities are concentrated in the core services, and consequently this is where the systematic search module will be incorporated. A large proportion of individuals who come to the one-stop centers are looking for job search assistance in the form of labor market information, assistance with preparing resumes, an initial understanding of the likelihood of finding a job, and what wage or salary level to expect. The first prototype FDSS includes algorithms for five programs: employment service, unemployment insurance, skill training, welfare-to-work, and veterans employment and

**Figure 12.1 Use and Cost of One-Stop Career Center Services under the Workforce Investment Act**

**Figure 12.2 One-Stop Center Client Flow**

training programs. To illustrate how these algorithms are constructed, this chapter focuses on the tools developed for displaced workers.

The systematic job search module includes three basic components to help job seekers become better informed about their job prospects and expected earnings. The first component, referred to as the industry transition component, estimates the likelihood that a customer can find a job in the industry in which they were previously employed. Obviously, this component is designed primarily to inform displaced workers about their job prospects. Research has shown that displaced workers tend to wait for jobs to open up in the industries in which they worked before displacement. Workers prefer to return to jobs with which they are familiar, and typically salaries are higher for those who stay in the same industry. However, in many cases, a worker was displaced because of general downsizing in that industry, which reduces the chances that a job in the same industry will become available. Waiting for such an event to occur increases the amount of unemploy-

ment insurance (UI) benefits the person will draw and reduces the likelihood of finding employment, even in another industry. The purpose of the systematic search module of FDSS is to help inform job seekers as to their prospects for finding jobs and to provide realistic assessments of likely compensation levels.

The need for a realistic assessment of expected reemployment earnings leads to the second component of the systematic search module—the earnings algorithm. The earnings algorithm is a statistical model that uses personal characteristics, work history, prior earnings, and educational attainment to predict earnings upon reemployment.

The third component is the related-occupations algorithm. The algorithm offers job seekers who have exhausted their likely job prospects within their prior occupation with a list of other occupations that are similar to their prior occupation. We offer different algorithms based on available data and show how they differ. More detailed descriptions of these algorithms are provided below.

The second module of FDSS is the service referral module. As mentioned in the overview of one-stop centers, a critical element for successful implementation of one-stop centers is staff ability to identify the needs of customers and to refer them expeditiously to services that best address their barriers to employment. Compounding this challenge is the possible lack of staff experience in serving a wide range of customers. The purpose of the FDSS service referral module is to compile and process information about the effectiveness of various alternative services in a way that better informs staff for referring customers to services. The service referral module uses information about the characteristics and outcomes of individuals who have recently participated in and completed services offered by one-stop centers. This information is used to estimate statistical relationships between personal attributes and outcomes. It should be emphasized that this module does not supplant staff referral decisions. Rather, it provides a means for staff to make better informed decisions.

The service referral module has two basic algorithms. The first is to estimate a person's employability, or likelihood of finding a job; the flip side of this is identifying an individual's barriers to employment. The second algorithm delineates the paths, or sequential combinations of services, that lead to successful outcomes. By conditioning these paths on the employability of a specific customer, the service referral

module can rank the likely effectiveness of various programs for individuals having specific observable characteristics.

## **TOOLS FOR THE SYSTEMATIC SEARCH ALGORITHM**

The systematic job search module consists of three tools: 1) the probability of return to the prior industry, 2) likely reemployment earnings, and 3) three alternative approaches to identifying occupations related to a prior one. For the first two tools, examples are provided for both Georgia and Washington using data on UI beneficiaries. The Georgia examples are for metropolitan Atlanta, and the Washington examples are for the south Puget Sound area. The third tool, identification of related occupations, is based on three sources: analyst ratings, national survey data, and Georgia Employment Service job placement data.

### **Return to Industry**

Many one-stop customers, particularly displaced workers, will switch employers. Prior research suggests that earnings losses will be minimized if the new job is in the same industry and occupation. As suggested by Becker's (1964) theory of human capital formation, the quickest way to return to the prior lifetime earnings path is to resume employment and begin building firm-specific human capital in a new job. To help clients more realistically assess job prospects, FDSS provides an estimate of the probability of returning to employment in their prior industry.

Reliable data are available from UI wage records in both Georgia and Washington to identify the industry in which the person was employed before and after displacement. Unfortunately, similar information is not available for an individual's occupation. Table 12.1 shows an industry transition matrix for UI clients in metropolitan Atlanta. Industries are separated into nine categories with the prior industry category in the left column and the reemployment industry along the top row. In each row, the largest element is on the diagonal of the matrix, indicating that the largest share of industry UI recipients return to work

**Table 12.1 Industry of Employment Transition Matrix: Percentage of Unemployment Insurance Clients, Metropolitan Atlanta, Georgia**

SOURCE: Based on data provided by the Georgia Department of Labor.

in the same industry. These aggregate average return probabilities range from 20.8 percent in agriculture, forestry, and fishery, to 73.3 percent in mining and construction.

Table 12.2 summarizes the percentage change in quarterly earnings for these industry employment changes in the Atlanta metropolitan area. The diagonal of Table 12.2 is positive for all industries except public administration, indicating that those who manage to be reemployed in their prior industry have earnings gains despite changing jobs. Similar patterns can be seen for south Puget Sound, Washington, in Tables 12.3 and 12.4. However, a larger share of UI claimants managed to be reemployed in their prior industry, and earnings growth was somewhat stronger in that region of Washington than in metropolitan Atlanta.

To provide individual estimates of the probability of being reemployed in the prior industry, we estimated logit models for each industry transition.<sup>1</sup> The logit model relates whether or not an individual stays in the same industry to a set of explanatory variables including prior earnings, age, educational attainment, the quarter of the year in which UI was applied for, and indicators for prior occupation.<sup>2</sup> The logit model also included variables that indicated whether an individual was a member of the following population groups: youth, veterans, currently employed, receiving public welfare assistance, and dislocated workers.<sup>3</sup> For Washington we were also able to include an indicator of union membership. Because of eligibility conditions, UI beneficiaries include very few people currently enrolled in school, so that category is not included.

Tables 12.5 and 12.6 provide examples of earnings models estimated on UI recipients in Atlanta and south Puget Sound whose prior job was in the manufacturing industry. Comparing parameter estimates across the two regions in the different states shows a large degree of consistency. In all cases where parameters on similar variables were estimated with adequate statistical precision, the estimates are of the same sign and similar magnitude. As an additional way of comparing the models, Tables 12.5 and 12.6 each consider the same three examples for evaluating the probability of returning to work in the manufacturing industry. Example 1 is a person aged 35, with a high school education, who earned \$30,000 per year in a clerical/sales occupation, and applied for UI in the second calendar quarter.<sup>4</sup> The probability of

returning to the same industry was estimated to be 0.294 in Georgia and 0.346 in Washington. The second example shows the Washington model to be much more sensitive to the prior earnings variable. Doubling prior earnings from \$30,000 to \$60,000 raised the chance of returning to manufacturing to 0.532 in south Puget Sound and only to 0.327 in the Atlanta area. The third example illustrates the same tendency for a lower prior annual earnings of \$10,000, with the probability in Washington falling to 0.114 and that in Georgia falling to 0.172.

### **Reemployment Earnings**

The WIA legislation permits intensive services to include “evaluation to identify employment barriers and appropriate employment goals” and also “the development of an individual employment plan, to identify appropriate employment goals, appropriate achievement, and appropriate combinations of services for the participant to achieve their employment goals.”<sup>5</sup> An underlying principle of WIA is that the best training is a job. Moderating wage expectations in order to gain a new job may be the quickest way to return to the prior earnings path. This establishes a need for a system like FDSS and requires that outcomes be judged relative to individual targets. FDSS provides an algorithm to estimate the expected reemployment earnings for each job seeker. By providing the job seeker with a realistic assessment of earnings prospects, he or she can conduct a more informed job search that can hasten employment.

Displaced workers and those who have had little attachment to the workplace, such as welfare recipients, may have little understanding of the earnings level that they might expect to find in the local labor market given their skills and opportunities. Displaced workers, for example, may expect to receive wages in their new jobs comparable to those in jobs they held prior to being displaced. However, recent research has shown that the earnings can drop by as much as 25 percent for workers who have found jobs after being displaced. Most of the loss in earnings is due to loss in value of firm-specific skills (Jacobson, Lalonde, and Sullivan 1993). It is important to point out that the FDSS earnings assessment is only suggestive. Job seekers who find the recommended target to be out of line with their expectations may discuss their differences with a staff person in the one-stop center. The staff

<sup>a</sup> Hypothetical worker 1: age 35, high school education, earning \$30,000 per year in a clerical/sales occupation, entering in the 2nd quarter of the year; hypothetical worker 2: age 35, post-high school education, earning \$60,000 per year in a clerical/sales occupation, entering in the 2nd quarter of the year; hypothetical worker 3: age 35, less than high school education, earning \$10,000 per year in a clerical/sales occupation, entering in the 2nd quarter of the year.

SOURCE: Based on data provided by the Washington State Employment Security Department.

person may use several means in addition to FDSS to establish a realistic earnings target, including past studies and current labor market conditions.

Quartile regression models are used to estimate earnings. The upper and lower bounds on the earnings range are set at the 25th and 75th percentiles, so one can think of this range as including earnings of half the people with similar measured characteristics. The model relates quarterly earnings to personal characteristics and labor market conditions. Many of these factors may be similar to those used by employment counselors to match job seekers to openings. The model assesses those factors in a systematic and consistent way so that customers with similar needs and characteristics are treated similarly.

The earnings models were developed using quarterly earnings data from UI wage records, which are the most reliable source of earnings data. However, workers do not usually measure their compensation in terms of quarterly earnings. Rather, earnings are typically expressed as hourly, weekly, monthly, and yearly rates of compensation. Converting the quarterly earnings to any of these other units is problematic, since wage records do not indicate the number of hours worked or even the number of weeks worked during a quarter. By using the maximum earnings in the year before and the year after receiving reemployment services, we anticipate that quarterly earnings will reflect full-time hours. Conversion from quarterly earnings to hourly earnings can then be achieved by applying the usual hours of work observed in each occupation and industry group using national survey data.<sup>6</sup>

For consistency of exposition, we report the results from the quartile regression models for the manufacturing sector in metropolitan Atlanta and south Puget Sound, the same regions and industry as used in the "return-to-prior-industry" models discussed above. As shown in Tables 12.7 and 12.8, the model includes variables typically used in earnings models, such as educational attainment, prior job tenure, occupation, and industry. Of course, the industry of reemployment is known only after a person finds a job. Since it is an endogenous variable, it would be appropriate to find an instrument for this variable, such as the industry transition regression described in the previous section. However, since our primary purpose is to construct a relatively simple model that offers the best prediction of future wages, we have not instrumented the variable. Instead, when predicting the earnings

for individuals we substitute the prediction of the likelihood the person will find a job in the same industry as a predictor in the earnings equation. Earnings models for Georgia and Washington also include age and age squared to capture the earnings cycle over one's working life.

Georgia data permit the inclusion of additional explanatory variables measuring tenure on the previous job, possession of a driver's license, availability for rotating shifts, employer attachment, current school enrollment status, and an individual's self-reported reservation wage. Washington data contain an indicator of union membership. Both models include indicator variables for population groups that are typically identified with the various programs offered by one-stop centers. These groups include youth, veterans, currently employed, receiving public welfare assistance, dislocated workers, and economically disadvantaged workers.

Results of the median regressions for the two models, as shown in Tables 12.7 and 12.8, are broadly consistent with previous earnings research. In both models, prior earnings, education, and age are positively correlated with future earnings, and occupation variables in prior employment are significant predictors of future earnings. In addition, returning to the industry of prior employment raises earnings by roughly 17 percent in both models, and the coefficient estimates are highly statistically significant. Indicators for the various population groups are not statistically significant except for welfare recipients in Washington and the economically disadvantaged and veterans in Georgia.

Coefficient estimates related to variables unique to each state add further insight into the determinants of a worker's compensation. For Georgia, results show that possession of a driver's license increases earnings. In addition, tenure on the previous job reduces earnings, which supports the results of WPRS models that detachment and subsequent loss of work experience reduces future earnings. On the other hand, those individuals with higher reservation wages receive higher future earnings, possibly because they know of skills and other personal traits not measured in the data that make them attractive to employers. In the Washington model, union membership raises earnings by 9 percent.

The purpose of the earnings algorithm is to estimate an earnings range for each one-stop customer. To do this, the regression coefficients are multiplied by the individual's characteristics. Consider again

the same three examples used above for evaluating the probability of returning to work in the manufacturing industry. Person 1 is 35 years old, has a high school education, earns \$30,000 per year (or \$7,500 per quarter) in a clerical/sales occupation, and applied for UI in the second calendar quarter. Median reemployment earnings for this individual in metropolitan Atlanta are predicted to be \$6,728 per quarter with lower and upper bounds of \$5,472 and \$8,179. A person with the same characteristics but living in the south Puget Sound area is expected to earn roughly the same amount: \$7,164 per quarter, with lower and upper bounds of \$5,615 and \$8,422. Consider Person 2, who is identical to Person 1 except that her prior earnings are doubled. This change has the effect of raising predicted median reemployment quarterly earnings in metro Atlanta to \$12,618 and in south Puget Sound to \$12,394. Person 3 has characteristics similar to the first two, except that prior annual earnings are \$10,000. For this example, predicted median reemployment quarterly earnings fall in metro Atlanta to \$3,387 and in south Puget Sound to \$3,450.

### **Related Occupations**

The FDSS algorithm identifying related occupations provides customers and frontline staff with a list of occupations that are related to the occupation that a worker most recently held. The purpose of the algorithm is to provide a customer who does not immediately find a suitable job match with job options in other occupations that require similar skills and aptitudes. Displaced workers are paid less upon reemployment than those who change occupations voluntarily, in part because of the poor match between their current occupational skills and current job. Providing customers with reliable information on alternatives to their previous occupation may improve their reemployment earnings and reduce the amount of time spent unemployed.

A study by Markey and Parks (1989, p. 3) found that “more than half of the workers in the United States who changed occupations did so because of better pay, working conditions, or advancement opportunities; however, about one in eight workers changed occupations because they lost their previous jobs.” Fallick (1993) found evidence that displaced workers increase the intensity of their job search in other industries when the employment growth rate in their previous industry is

low. Shaw (1987) estimated that a 25 percent increase in the transferability of occupational skills leads to an 11 to 23 percent increase in the rate of occupational change, depending on the age of the worker. Taken together, these results suggest that workers concentrate their search efforts in industries and occupations similar to their own. A reasonable reemployment strategy might include identifying related occupations and providing clients with timely information on the prospects for work in those areas.

Two methods are used to identify related occupations. The first methodology, based on the O\*Net system, chooses occupations that are considered to be closely related to the previously held occupation with respect to a person's qualifications, interests, work values, and previous work activities, to name several of the attributes. O\*Net, developed by the U.S. Department of Labor, incorporates the expert opinions of human resource professionals and analysts as to the characteristics of each of more than 1,000 occupations and then relates the various occupations by prioritizing the importance of these attributes for each occupation. This methodology addresses the decision to change occupations by asking the question, "What occupations are most related to my previous occupation with respect to my qualifications, interests, and aspirations?" This approach assumes that the person was qualified for the job that he or she previously held. O\*Net matches the characteristics of the previous job with the characteristics of other related occupations. However, these transfers are hypothetical and are not based on actual occupational transfers. It does not take into account the actual demand for a worker's skills.

The second methodology is based on actual occupational changes and addresses the transfer decision with the following question: "For workers who switch out of my occupation, into which occupations do they most frequently move?" This methodology provides a worker with insights into the set of jobs that people like him most often obtain. It incorporates both the qualifications of workers and the demand for their skills. Two data sets are used to record job changes and to compile the list of occupational transfers. The first data set is the Current Population Survey (CPS), which is a national survey of households taken each month. The second data set is the administrative files from the Georgia employment service, which includes self-reported work histories of each participant. Unfortunately, Washington employment ser-

vice records could not be used because they do not include occupation codes.

Each methodology has its advantages and disadvantages. The first methodology is based on extensive information about the characteristics required by an occupation. Furthermore, because of its comprehensive assessment of skill requirements for specific occupations, this methodology allows one to link this information to possible course offerings at local training and educational institutions in order to fill specific skill gaps. The information can also be used to assist in determining the services that best meet the individual's needs and then to make the appropriate referral. The tools can help determine not only which programs are appropriate for the customer, but also which services within a particular program may be most effective.

However, one of the major drawbacks of this first methodology is that it does not consider the demand by employers for those skills embodied in the occupation. For instance, the occupation that O\*Net determines to be highly related to a worker's previous occupation may be a good match with respect to skills, but there may be little demand for that occupation in the local labor market.

The primary advantage of the second methodology is that it incorporates both supply and demand considerations inherent in job changes. By using local data, it can provide a convenient perspective on the occupations within which a person is most likely to find a job. Its drawback is the lack of detailed information about the occupation. There is little information about the qualifications of those who hold a job in that occupation, except for information about educational attainment. Some of the deficiencies of this methodology with respect to detailed occupation information may be addressed by combining the two approaches.

To illustrate the two approaches, we found occupations related to the occupation of bookkeeping, accounting, and auditing clerks (O\*Net Occupation Code 43-3031.00).<sup>7</sup> As shown in Table 12.9, O\*Net identified occupations that appear to be closely related in terms of the type of tasks required and the level of autonomy in executing the tasks—elements which O\*Net focuses on in categorizing occupations. Table 12.10 shows the matches of people who switched from computing and account recording to other occupations, as recorded in the Georgia employment service records. While the majority of job switchers stayed

**Table 12.9 Related Occupations for Bookkeeping, Accounting, and Auditing Clerks**

O*Net occupation title	O*Net occupation code
Billing, cost, and rate clerks	43-3021.02
Billing, posting, and calculating machine operators	43-3021.03
Brokerage clerks	43-4011.00
Loan interviewers and clerks	43-4131.00
Secretaries (except legal, medical, and executive)	43-6014.00
Office clerks, general	43-9061.00

NOTE: The O\*Net occupation code for bookkeeping, accounting, and auditing clerks is 43-3031.00.

SOURCE: O\*Net Online (<http://online.onetcenter.org>).

within the same occupation, the next most prevalent job change was to the occupation of packaging, and materials handling. This choice of a related occupation seems strange, but it most likely reflects the prevalence of job openings in the area for people with the skills embodied in the occupation of computing and accounting. Changes to occupations more related to record keeping also took place. Job changes recorded using CPS data as reported in Table 12.11 reveal occupations more closely aligned to record keeping than found for the Georgia data. Most of these occupations are considered clerical, except for teachers. The difference between the two data sets results perhaps from the industrial mix of jobs in local labor markets, which is not captured in national data such as the CPS.

## **SERVICE REFERRAL ALGORITHM**

The second module of FDSS is the service referral algorithm. As mentioned in the overview of one-stop centers, a critical element for successful implementation of one-stop centers is the staff's ability to identify the needs of customers and to refer them expeditiously to services that best address their barriers to employment. Compounding this challenge is the possible lack of experience among the center's

staff in serving a wide range of customers. The purpose of the FDSS service referral module is to compile and process information about the effectiveness of various programs in a way that better informs staff when referring customers to services.

The service referral module is based on information about the characteristics and outcomes of individuals who have recently participated in services offered by one-stop centers. These data are used to estimate statistical relationships between personal attributes and outcomes. The service referral module uses these models to identify the sequence of services that most often leads to successful employment outcomes for individuals with specific characteristics. It should be emphasized that this algorithm does not replace the staff's referral decisions. Rather, it provides additional information to better inform the decision.

The effectiveness of alternative paths for each customer depends upon their employability. Therefore, the service referral algorithm has two basic components. The first is a model to estimate a person's employability, or likelihood of finding a job. Conceptually, this is the flip side of WPRS models, which identify the chance of UI benefit exhaus-

tion. The second component is a delineation of the paths, or sequential combinations of services, that lead to successful outcomes. By conditioning alternative services on the employability of a specific customer, a ranking can be produced of the effectiveness of various programs for individuals with specific measurable characteristics. This ranking would be a suggested ordering of service participation.

Since it is based on prior values of exogenous variables, the employability index can be viewed as a summary of client characteristics. Interacting the employability index with service indicators is a type of subgroup analysis (Heckman, Smith, and Clements 1997). The planned approach is analogous to that used by Eberts in Chapter 8 of this volume (p. 221) for assigning welfare-to-work clients to alternative bundles of reemployment services. This method is also similar to the procedure applied in this volume by O'Leary, Decker, and Wandner (p. 161), who essentially interacted an unemployment insurance benefit exhaustion probability index with reemployment bonus intervention indicators to identify the best exhaustion probability group for targeting a bonus.

The exercise of O'Leary, Decker, and Wandner reexamined treatment and control group data generated by random trials in a field experiment. However, service referral algorithms for FDSS are based on administrative data in which program participation is subject to selection bias. So that the effectiveness of alternative services may be ranked for customers with different employability scores, impact estimates will be computed while correcting for selection bias. We plan a simple single-equation least squares methodology, which will be validated by a matching approach that accounts for all possible nonlinear influences of observable factors on selection for program participation (Rosenbaum and Rubin 1983; Heckman, Ichimura, and Todd 1997; Heckman, LaLonde, and Smith 1999; and Smith 2000).

### **Employability Estimates**

This algorithm estimates the likelihood of an individual finding employment based upon prior work history, personal characteristics, and educational attainment. The estimate is based on the experience of individuals who have recently enrolled with the employment service or with other programs provided through one-stop centers. However,

since we are assessing their initial employability before receiving services, we estimate the model using only those persons who have not yet received services within their current enrollment period.

The data come from the same administrative records that are used to estimate the components of the systematic job search module described in the previous section of this chapter. The employability model is similar to the earnings algorithm, except that employment is used as the dependent variable instead of earnings. Thus, the sample includes individuals who have worked just prior to enrolling in one-stop programs, as well as those who have not held a job prior to enrolling. In this way, we are able to compare the measurable attributes of those with and without recent employment as they enter a one-stop center. The presumption is that those with more recent work experience are more employable, even before they receive services.

For illustrative purposes, an employability model for welfare recipients in the State of Washington is discussed. The explanatory variables include prior work history, educational attainment, participation in public assistance programs, and their primary language. As shown in Table 12.12, the coefficients display the expected signs and many are statistically significant. For instance, people who have experienced longer periods of unemployment are less likely to hold a job at the time of intake. People with more education are more likely to hold a job. Those who are willing to relocate are also more likely to find employment. Based on these variables and others, the probability of employment is predicted for each individual who enrolls in Work First. The next step is to determine whether or not some services are more or less effective for individuals within certain ranges of the distribution of employment probabilities.

### **Path Analysis**

The second component of the service-referral module is an analysis of the various services that individuals receive to assist their efforts in searching for and obtaining a job. As discussed in the section on the flow of clients through one-stop centers, it is apparent that individuals typically receive more than one service during their participation period and that they receive those services in various sequences. For instance, a welfare recipient may start his or her participation in the Work

First program by being referred to the program by the welfare (or social service) agency, then being referred to a job search workshop, then to a basic education program, and then back to a job search initiative. The final steps would be a job interview and employment. Even after obtaining a job, the individual may participate in postemployment activities. Another welfare recipient entering the same program may take a different route to employment.

Therefore, for programs that offer a sequence of services, the analysis must identify the predominant paths that participants typically follow. Considering a collection of individual activities, such as attending a job search workshop or enrolling in an education program (without taking into account how they relate to other activities) does little to capture the cumulative nature of the delivery of services. Once the pathways, or sequence of service activities, have been identified, the effectiveness of these strings of services will be analyzed with respect to each individual's estimated likelihood of employment. One would expect to find that specific paths are more effective in leading to employment for some individuals than others, depending upon the individual's propensity for employment as measured by the estimated employability.

For Work First, the pathways are relatively short. In some cases, participants receive only one service before finding employment or otherwise exiting the program. Table 12.13 shows a sample of paths from two starting points. The top portion of Table 12.13 includes those who were referred to the Employment Security Department (ESD) during their participation in Work First. The bottom portion includes those who returned to Work First after working for a while but then losing their job. The specific activities are not important for the purpose of illustrating the paths.<sup>8</sup> Rather, the important point is that definite sequences of activities occur and that many of these paths consist of only one recorded activity.

### **Estimates of the Effect of Services on Employment Outcomes**

To illustrate the effect of specific services on employment outcomes, we estimate a model that relates employment in the quarter after exiting from the program to participation in services and other char-

acteristics, including the predicted probability of employment derived from the employability model. We focus on the two most prevalent services received by those returning to Work First—employment retention services and labor market exchange (WPLEX). We interact the predicted employability estimate for each individual with a variable indicating whether or not they received either one of the two postemployment services.

Results in Table 12.14 show that returnees who have participated in WPLEX and postemployment retention services are more likely to find a job and stay off of welfare than those who do not participate. Furthermore, WPLEX is more effective for those who have a higher probability of employment than those with a lower probability, according to the employability estimate. Therefore, while the magnitudes of the effects are small, the estimates do offer information about the appropriate services for individuals with certain characteristics. The service referral algorithm will follow a similar approach in estimating the effect of services offered by other programs.

## SUMMARY

The Workforce Investment Act of 1998 calls for the creation of a national network of one-stop centers where intake and referral of job seekers to various programs will be done in a coordinated fashion. Resource constraints dictate that each workforce development program can serve only a portion of the population which might benefit. Funding levels, from state and federal sources, determine how many workers can be served. Choosing which individuals are served depends on decision rules applied by frontline staff in one-stop centers. By targeting services to job seekers who will benefit the most, statistical tools can help make these decisions more cost-effective for society, thereby maximizing the net social benefit of program expenditures.

The Frontline Decision Support System offers a variety of tools that can help inform staff and customers in their job search efforts and in their selection of reemployment services. The tools are based on statistical techniques that use administrative data to estimate likely earn-

ings prospects, industry transitions, related occupations, and outcomes associated with participating in specific reemployment services. FDSS is an extension of previous methods like the Worker Profiling and Reemployment Services system, which all states have implemented, and the Work First pilot, which was implemented at the Kalamazoo-St. Joseph, Michigan, Workforce Development Area. At the time of this

writing, the W.E. Upjohn Institute is working closely with the states of Georgia and Washington to design and implement FDSS in selected one-stop centers.

## Notes

We thank Helen Parker and Richard Hardin and participants at the Targeting Employment Services conference, Kalamazoo, Michigan, April 30–May 1, 1999, for constructive comments that helped to improve this chapter. For research assistance we thank Wei-Jang Huang, Ken Kline, and Kris Kracker. Clerical assistance was provided by Claire Black, Nancy Mack, and Phyllis Molhoek. Opinions expressed are our own and do not necessarily represent those of the W.E. Upjohn Institute for Employment Research. We accept responsibility for any errors.

1. Logit models were widely used by states as a basis for Worker Profiling and Reemployment Services (WPRS) assignment rules. Eberts and O’Leary (1996) provided an example from Michigan.
2. Age, gender, and race were prohibited variables in WPRS models. However, unlike WPRS, the FDSS system does not set criteria for program eligibility. The graphical user interface for FDSS computer screens in one-stop centers will not display age, gender, and race as variables on which “what if” scenarios can be examined. These variables were included because statistical tests indicated that excluding these variables would introduce an omitted variables bias in estimation of other model parameters, following the work of Kletzer (1998) and others.
3. These categories are defined by employment service practice. The dislocated worker definition is consistent with that in the Economic Dislocation and Worker Adjustment Assistance Act (EDWAA) of 1988. The EDWAA definition includes those with significant prior job attachment who have lost their job and have little prospect of returning to it or to another job in a similar occupation and industry.
4. Note that the earnings variables in the models are quarterly figures, not annual figures.
5. Section 133(d)(3)(i) and (ii), Workforce Investment Act, Public Law 105-220–August 7, 1998. U.S. Congress (1998, Section 134[d][3][c]).
6. Using data from the Current Population Survey for a comparable time period, we computed a (9 × 9) industry-occupation matrix of average hours worked using one-digit industry and occupation groups.
7. In making the comparisons, considerable effort was required in converting the occupation codes from O\*Net to the occupation codes used in the CPS and by the Georgia Employment Service. Complete matching was not possible, but we came as close as possible. See DeRango et al. (2000) for more details.
8. A detailed discussion of these paths is given by Eberts, O’Leary, and Huang (2000).

## Comments on Chapter 12

Helen Parker

*Georgia Department of Labor*

The concept of using statistical profiling (targeting) on the front line of the one-stop system emerging under the Workforce Investment Act of 1998 (WIA) is a significant and timely development. The Front-line Decision Support System described by Eberts, O’Leary, and De-Rango will help ensure both effective customer service and efficient use of resources in the new integrated environment. Its dual usefulness as a management tool and a staff/customer resource makes FDSS a versatile and valuable addition to the one-stop service delivery “toolkit.”

As Eberts and O’Leary point out, FDSS will be an excellent management tool for resource allocation and continuous improvement. At the same time, it provides a much needed service for staff to help ensure that customers receive the services they really need—no less and no more. At a time when the workforce development system is moving away from “one size fits all” services and toward the customer-focused, customer-led service strategies envisioned by the WIA, this targeting approach should facilitate, perhaps even force, individualized customer-by-customer decision making. With both the customer and the staff armed with better information, service tailored to the unique needs of the individual is not only achievable, but it becomes the norm.

FDSS may also help us prevent what may be an unanticipated consequence of the WIA’s perceived “work first” philosophy and delineation of what some call “sequenced” services. The WIA describes three levels of services—core, intensive, and training—and would seem to suggest, as Eberts and O’Leary note, that lack of success in obtaining employment is the criterion for moving from one level to the next. This creates an impossible—and decidedly *not* customer-friendly—scenario that requires a customer literally to fail his way into need-

ed services. Because it helps the customer and staff identify both barriers and needed services very early in the service continuum, FDSS should enable staff to identify situations in which core services clearly will not suffice, and to help those customers move more quickly into interventions that will lead to employment.

FDSS should also be particularly helpful when there is an economic downturn, when demand will outstrip available resources even more. Higher unemployment not only increases customer demand for services, it increases the demand for more staff-intensive services. A targeting tool like FDSS can help staff more quickly and more thoroughly assess and guide their customers.

While FDSS will be an extremely valuable tool for both staff and management, it does not come “worry-free.” The description of this tool and its potential uses raises several concerns. First, the system must be designed with maximum flexibility, so that it can be used in a wide variety of settings and with an equally wide variety of automated systems. The Upjohn Institute seems to have anticipated this by planning another version of the product for states and local areas that do not use the federally supported one-stop operating system.

Using wage records both to target jobs and to help determine cost-effectiveness may prove rather limiting. The wage records by themselves may be inadequate to give a true sense of an earnings range, and the lack of real-time data will limit the usefulness of that aspect of the tool. From a customer service standpoint, the wage range itself may create customer dissatisfaction in screening for jobs: neither the customer who will settle for lower pay nor the one who demands access to higher wages jobs—and there are many of both—will be satisfied with the results. Development of a meaningful cost/benefit analysis may also prove a challenge. While the costs of training have traditionally been fairly easy to identify, the costs of other “softer” services like counseling, workshops, and case management may prove difficult. In the integrated one-stop system envisioned by the WIA, distinguishing between shared system costs toward which all partners contribute and program-specific costs for services, which may also be split across more than one fund source, may well hinder accurate determination of costs. The benefit side is equally complex; earnings, or “narrowing the earnings gap,” is only one aspect of the benefit measurement and is

likely to be inadequate unless both labor market and wage information are more up to date and more market-specific.

In developing and implementing FDSS, the U.S. Department of Labor and the Upjohn Institute will need to confront the tensions inherent in the service delivery approach mandated by WIA. Perhaps most troublesome is the tension between “most in need” and “most likely to benefit.” The pull between these two has always been a frustrating reality in performance-driven systems like those under the Job Training Partnership Act. WIA does not relieve that potential for conflict, and in fact it may exacerbate it as local areas struggle to meet the spirit of the law with limited resources. The ability of a staff member or a local board to target customers and services hinges on determining whether need or benefit receives priority. If developed with an awareness of that dilemma, FDSS may well offer at least a partial solution.

A second tension, and one that FDSS designers may not yet have considered seriously enough, stems from the very clear mandate in WIA for customer choice in decisions about services and training. The concept of targeting and the decision-making tool itself may assume a level of staff intervention or control that could be difficult to achieve. For mandatory customers, such as profiled UI claimants and welfare recipients, staff interventions might be tolerated more readily. But customers who simply want to access some mix of services and/or training, particularly those who already have expectations about the services they want, may require more staff time to guide them than the system has the capacity for or than is cost-effective.

We also need to guard against the use of a tool like FDSS inadvertently reinforcing the tendency of workforce development and human resource development systems to assume that we know better than the customer what is best for him or her. If one goal of WIA is to empower the customer to make informed choices, this new tool needs to be as customer-friendly as possible, and our staff need to be thoroughly trained in what the FDSS is and what it isn't. Indeed, the “selling” of this new tool and staff training on its uses are of paramount importance. As with the development of Service and Outcome Measurement System in Canada, buy-in by management, and particularly by frontline staff, is absolutely critical if the product is to reach its true potential. We must also be sensitive to the very human reactions that staff and

customers may have to such a system, and this too must be a part of the selling of and training for the product.

Some staff and customers will feel threatened by such a tool. Other staff are likely to use it as a shield behind which they can hide from interaction with customers; it was, after all, the computer that made the decision, as they see it. Still others will see the system's targeting recommendations as directives, not guidance, and will forego the role that a professional staffer should play in helping a customer make good decisions.

A colleague of mine likes to describe the delivery of employment services as a "high tech, high touch" business. FDSS has the potential to address both. If it is developed as planned, it can add a level of sophistication and flexibility that the emerging workforce development system will need for effective service. It can enable staff to assist and guide their customers, and empower customers to make more informed choices about their service needs. We just need to take care that, with FDSS or any other such tool, "high tech" doesn't substitute for the "high touch" that many of our customers need and want.
